**TOPIC:-** Group-wise systematic study of p-block elements

Group-13 Hydrides

#### Hydrides

The elements form tri-hydrides (MH<sub>3</sub>), the stability decreases on moving down the group. They are electron deficient compounds. Boron forms a series of volatile hydrides called boranes (by analogy with alkanes and silanes). They fall into two series:

```
\begin{split} &B_n\,H_{n+4}\colon B_2H_6,\,B_5H_9,\,B_6H_{10},\,B_8H_{12},\\ &B_{10}H_{14}\,B_n\,H_{n+\,6}\!\!\colon B_4H_{10},\,B_5H_{11},\,B_6H_{12},\\ &B_9H_{15} \end{split}
```

They are named by indicating the number of boron atoms. If two or more boranes have the same number of B atoms, then the H atoms are also specified, e.g.  $B_5H_9$  and  $B_5H_{11}$  are named pentaborane – 9 and pentaborane – 11 respectively.

Diborane is the simplest and most extensively studied hydride. It is an important reagent in synthetic organic chemistry. It may be prepared by various ways:

Diethyl Ether

 $4BF_3.OEt_2 + 3LiAIH_4 \longrightarrow 2B_2H_6 + 3LiF + 3AIF_3 + 4Et_2O$ 

#### Boron tri-fluoride etherate

Diglyme

 $2NaBH_4 + I_2 \longrightarrow B_2H_6 + 2NaI + H_2$ 

Sodium borohydride

 $2NaBH_4 + H_2SO_4 \quad 2H_3PO_4 \longrightarrow B_2H_6 + 2H_2 + Na_2SO_4 \quad 2Na_2HPO_4$ 

It is a colourless gas, which burns in air and is readily hydrolyzed.

 $B_2H_6 + 3O_2 \rightarrow B_2O_3 + 3H_2O$ 

B<sub>2</sub>H<sub>6</sub>+ 6H<sub>2</sub>O → 2H<sub>3</sub>BO<sub>3</sub> + 6H<sub>2</sub>

Diborane undergoes addition reaction with alkenes and alkynes in ether at room temperature to form organo-boranes.

 $6RCH = CH_2 + B_2H_6$   $\rightarrow$   $2B(CH_2CH_2R)_3$ 

This is known as hydroboration reaction. The structure of diborane is of great interest as it is an electron deficient compound having only twelve electrons, which are insufficient to form the required number of bonds. Each boron has three electrons and can form a BH<sub>3</sub> unit each but how will the two units be held together?

Diborane is found to have a bridge structure in which each B atom is bonded to two H atoms (called terminal H atom) by regular electron pair bonds. The resulting two BH<sub>2</sub> units are bridged by two H atoms (the bridge H atoms), which are at a plane perpendicular to the rest of the molecule and prevent rotation between the two B atoms. The structure has been confirmed by electron diffraction, infrared and Raman spectroscopic methods. Four hydrogen atom are in an environment different from the other two – this is confirmed by Raman spectra and by the fact that diborane cannot be methylated beyond the tetra methyl derivative without breaking the molecule into BMe<sub>3</sub>

The terminal B-H bond distances are the same as in nonelectron deficient compounds. These are normal two centre two – electron bonds (2c-2e). Electron deficiency is thus associated with the bridge bonds. The four bridge bonds involve only four electrons – a pair of electrons is involved in binding three atoms – B, H and B. these bonds are called three-centre-two- electron-bonds (3c-2e).

Each B atom is sp<sup>3</sup> hybridized giving four sp<sup>3</sup> hybrid orbitals. B has three valence electrons so three orbitals are filled singly. Two of the sp<sup>3</sup> hybrid orbitals on each B overlap with the 1s orbitals of H forming four 2c - 2e bonds.

Then one singly filled  $sp^3$  hybrid orbital on one B atom, and one vacant  $sp^3$  hybrid orbital on another B atom overlap with a singly filled 1s orbital on one H atom to form a bonding orbital shaped like a banana embracing all three nuclei Another 3c - 2e bond is formed similarly (fig 3)

Diborane

Most syntheses of the higher boranes involve heating  $B_2H_6$ , sometimes with hydrogen. Most of the higher boranes are liquids but  $B_6$   $H_{10}$  and  $B_{10}$   $H_{14}$  are solids. They were considered to be potential rocket fuels, but interest in this was soon diverted as it was found that on combustion they formed a polymer, which blocked the nozzles.

The higher boranes have an open cage structure (fig4). The structures involve 2c - 2e bonds between B and H and B - B and 3c - 2e bonds involving B-H-B and B-B-B. Closed 3c-2e bonds of the type are also known.

#### **Borohydrides**

Borohydrides like NaBH<sub>4</sub>, Al(BH<sub>4</sub>)<sub>3</sub> contain the tetrahydroborate (III) anion, BH<sub>4</sub>. In these

compounds boron has a complete octet and thus they are more stable than the boranes. Sodium borohydride is obtained by the reaction between sodium hydride and methyl borate.

4NaH+B(OMe)<sub>3</sub> NaBH<sub>4</sub> + 3CH<sub>3</sub>ONa

Other borohydrides may be obtained from NaBH<sub>4</sub>. The BH<sub>4</sub> ion has a tetrahedral structure, NaBH<sub>4</sub> is a useful reagent used in reduction of aldehydes and ketones.

#### **Hydrides of other members**

Other members of Group 13 form a few hydrides which are polymeric in nature e.g.  $(AlH_3)_n$ ,  $(GaH_3)_n$  and  $(InH_3)_n$  and contain M-H-M bridges. Their stability decreases on moving down the group.  $(AlH_3)_n$  is the best known and is prepared by the action of pure H<sub>2</sub>SO<sub>4</sub> or Al Cl<sub>3</sub> on lithium aluminium hydride in ether.

2LiAlH<sub>4</sub> + H<sub>2</sub>SO<sub>4</sub> \_\_\_\_\_ 2/n (AlH<sub>3</sub>)<sub>n</sub>+LiSO<sub>4</sub>+2H<sub>2</sub>

3LiAlH<sub>4</sub> + AlCl<sub>3</sub> + 4/n (AlH<sub>3</sub>)n + LiCl.

It is a colourless and thermally unstable solid and reacts violently with water.

2(AlH<sub>3</sub>)<sub>n</sub> + 6<sub>n</sub>H<sub>2</sub>O 2nAl(OH)<sub>3</sub>+ 9n H<sub>2</sub>

A complex hydride of aluminium, lithium aluminium hydride is well known. It is prepared from lithium hydride and aluminium chloride in ether.

It is a powerful reducing agent and is widely used in organic chemistry. The borohydrides of aluminium, beryllium and the transition metals are covalent. In Al  $(BH_4)_3$  each  $BH^-$  unit forms two hydrogen bridges while in Be $(BH_4)_2$  each  $BH^-$  unit forms three hydrogen bridges
