

Theorem If $V(F)$ is a finite dimensional vector space ($F \Delta VS$). Then a bilinear form f on V is symmetric or antisymmetric (skew-symmetric) according as the matrix of f in any ordered basis is symmetric or antisymmetric.

Proof: Let B be an ordered basis of $F \Delta VS$ $V(F)$. Let f be a bilinear form on V and $u, v \in V$.

Let A be the matrix representation of f relative to basis B . Also let X and Y be co-ordinate vectors of u, v relative to the basis B . Then, we have

$$f(u, v) = X'AY \quad \text{--- (i)}$$

$$f(v, u) = Y'AX \quad \text{--- (ii)}$$

As $X'AY$ is a 1×1 matrix [i.e. X' is $1 \times n$ matrix, A is $n \times n$ matrix, and Y is $n \times 1$ matrix], therefore

$$X'AY = (X'AY)' \quad \because A = A' \text{ for sym.}$$

$$X'AY = Y'A'(X')' \quad \because (AB)' = B'A'$$

$$X'AY = Y'A'X \quad \text{--- (iii)} \quad (A')' = A$$

from (i), we get $f(u, v) = Y'AX$

Case (i) if f is symmetric then $f(u, v) = f(v, u)$

$$\text{from (i) \& (ii)} \quad X'AY = Y'AX \quad \text{--- (iv)}$$

$$\text{from (iii) \& iv} \quad Y'AX = Y'A'X \quad \forall X, Y$$

$$A = A'$$

$\Rightarrow A$ is symmetric.
Thus f is symmetric $\Rightarrow A$ is symmetric.

Case (ii) when f is anti-symmetric

$$\text{Then } f(u, v) = -f(v, u) \quad \text{--- v}$$

from (i) & (ii)

$$X'AY = -Y'AX \quad \text{--- (v)}$$

from (iii) & (vi)

$$Y'A'X = -Y'AX$$

$$A' = -A \quad \text{or} \quad A = -A'$$

Hence f is antisymmetric $\Rightarrow A$ is anti-symmetric.

Finally, f is symmetric or anti-symmetric

$\Rightarrow A$ is symmetric or anti-symmetric.

$$\text{--- } X'AY = (u, v) \text{ ---}$$

$$(YA'X) = X'AY$$

$$(X)A'X = X'AY$$

$$X'AY = X'AY$$

$$X'AY = (u, v) \text{ ---}$$

$$X'AY = X'AY \text{ ---}$$
